Adding transitive string C-groups to Topic B
Complete measurement inputs

Input proposal; distinct count review pending

12 October 2026

This packet prepares a six-original manuscript comparison. It contains no compression factor and makes no new scientific or question claim. The corrected L047 principal contract has separate scientific review and root adoption; measurement acceptance is a separate step.

The complete boundary. The five existing originals are N001, N003, N008, L030 and L040. L047 is added as B6. Every existing source and replacement observation stays exact. N001 remains the complete literal authored rendering, not an acquired original PDF. The other five originals use their fixed complete PDFs. L040 retains its identification cover in the primary, with its accepted direct article-only sensitivity preserved.

The replacement has two complete common papers: the existing sixteen-page *Forest coordinates and relative generation* and the ten-page *String separators, normal modules and transitive rank*. It retains all five existing applications and adds the complete three-page *Transitive string C-groups: the complete half-degree bound*. Both whole common papers are acquired once within Topic B; no unused passage is deducted merely because the new proof avoids an older argument. The full finite-neighbor proof is already written in the new common paper. Its archived two-page predecessor is provenance, not a second manuscript charge.

Fixed units. The primary remains raw, untrimmed NFC characters without whitespace, selected before new counts. All thirty coordinates are retained: raw untrimmed, raw selected and calibrated selected text; NFC and NFKC; and five units (whitespace tokens, alphanumeric units, nonspace characters, collapsed-space characters and collapsed-space UTF-8 bytes). Titles, proof prose, tables, references and qualifications remain within the complete manuscripts.

New complete document	Pages	Raw primary	Calibrated
Complete L047 original	12	19,971	19,389
Complete new common theory	10	29,398	29,387
Complete new application	3	5,503	5,500
Separate complete program appendix	7	16,472	16,465

The calibrated column is the selected NFC nonspace sensitivity, not a preferred replacement for the fixed raw primary. The program appendix is an inventory representation and is excluded from both manuscript sides.

Matched software treatment. L047 names Magma computations and a primitive-group catalogue function, but contains no complete executable listing. Its full source and all new scientific pages were read and visually checked. The replacement likewise keeps its mathematical algorithms as prose; executable code is in separate appendices. The accepted listing screen for the older five originals and their current applications is reused without a new exclusion or extraction.

There are ten whole mathematical files: four inherited files and six additional required finite inputs. Of the old four, two supply required or auxiliary finite premises and two are optional validations. All six additional files are required: the four new complete searches, the inherited finite-neighbor search, and its exact action roster. A file called `run.g` is therefore a mathematical input, not merely an operational launcher. No additional stored data are consumed by these files. Their recorded results and complete logs are reproducible execution receipts; GAP algorithms and catalogue completeness remain retained premises.

The two seven-page appendices print all ten files in full. The whole raw files are an alternative representation, never an added second charge. Five operational drivers and two inherited Lean modules are inventoried separately; the latter contain fourteen partial declarations and zero new declarations. Four archived independent-audit tools are separately identified as provenance. No complete source formalization is claimed.

Optional validation is excluded on both sides. Required finite certificates retain their mathematical role, so a future manuscript-length ratio will not be a complete executable-proof cost. Source-side software, complete external proofs and complete graphics have unknown cost, not zero. No software-inclusive scalar is available. Any conditional comparison must first acquire both whole common papers and every required dependency.

Glyphs and graphics. The new source and new replacement use actual font dictionaries and encoded glyph events. Eight private outline panels cover 85 distinct embedded classes. Twenty-three alias classes give 314 individually bound repairs: two source epsilon events and 312 symbols in the new common paper. Repairs affect only the calibrated sensitivity. A mapsto tail stays separate from adjacent arrow components. The standard unembedded font used in the source's arXiv banner stays literal; no embedded-outline claim is made for it. Three code-wrap symbols also stay literal in every measured variant; the hook's extraction is a representation limitation. They are ignored only in the separate test that each complete raw file is printed.

Table values are retained as text. Table rules, layout and other graphics have no invented text equivalent. The entire source Table 3 remains counted, including its 23 finer reports that are ancillary to the accepted principal contract. Source Conjecture 1.1 was already resolved in L044; this packet claims no new question solution.

Review and reproducibility. The proposal preserves 360 previous document cells, 30 article-only sensitivity cells and 80 raw-file cells. It adds 120 document cells and 90 raw-file cells. The resulting main boundary has 450 PDF cells and 30 literal-rendering cells, with 170 raw-file cells separately inventoried. All fifteen PDFs contain 134 pages; no original PDF is invented for N001. The input author wrote the older B common theory and distinctly reviewed L047 science. Those roles are disclosed; new metric acceptance must come from a different reviewer. Replay extracts inputs and rebuilds this reader without rerunning finite searches or Lean.
