Inputs for the unified theory of coset geometries and symmetric group markings

Human Compression project

Measurement boundary awaiting independent review

The comparison covers the same five originals and sixty-five source clauses as the admitted Topic B edition. This packet fixes inputs only: it does not calculate a compression factor or change any scientific credit. The complete new common paper replaces the two earlier common papers through independently reviewed proofs; no passage is removed merely because it resembles an earlier proof.

Complete current document	Pages	Nonspace characters
Common theory	16	44,905
Inductively minimal geometries	3	7,371
Maximal symmetric markings	4	9,155
Frattini coordinate geometries	4	11,132
Disjoint-subset geometries	5	12,286
High-rank symmetric markings	11	29,321
Complete program appendix	7	13,170

These are raw, untrimmed PDF extractions under NFC normalization. All fifty pages, titles and references are included. The common paper is charged once and every complete application is charged. The printed four-program appendix and the four entire raw files are alternative representations, never two additive charges. Any later conditional application comparison presupposes acquisition of the whole common theory and all four programs.

The five original costs and all thirty policy coordinates are retained exactly from the accepted B5 baseline. N001 uses its complete literal authored-browser rendering; its original PDF remains unavailable. N003, N008, L030 and L040 retain their bound complete PDF editions. L040's identification cover remains in the primary coordinate; the earlier direct article-only sensitivity is retained separately.

Two current operational drivers and two Lean files are inventoried separately. The fourteen reused declarations remain partial formal evidence. One program supplies bounded primitive-group inputs, two validate written general arguments, and one supplies the separate degree-eight example and validates the branching correction. Their roles do not change because all four are printed and charged.

All used font dictionaries, encodings and glyph outlines are bound. No replacement glyph substitution is needed. The two selected sensitivities remove only exact page-number footers; code wrap symbols remain literal in measured text. Full graphic complexity, unpriced external proofs and historical software remain unknown. The input author also performed the preceding distinct scientific review; this numerical proposal still requires an independent input review.
