Coset geometries and symmetric group markings: unified proof costs

Human Compression project

Numerical candidate awaiting independent review

The complete written comparison for the five fixed original texts is

$$\frac{\sum_i c(L_i)}{c(U_B) + \sum_i c(B_i)} = \frac{124,906}{44,905 + 69,265} = \frac{124,906}{114,170} = \mathbf{1.094035}.$$

The numerator keeps the accepted source representations: N001's complete literal authored-browser rendering and the four complete PDFs. N001's original PDF remains unavailable; no complete-PDF factor for all five originals is claimed. The L040 identification cover remains in the primary input.

The entire sixteen-page common paper is charged once. It replaces the two earlier common papers through reviewed mathematical arguments, and all five complete applications remain. The fifty-page current input bundle includes references and the seven-page complete program appendix.

Matched original	Original	Application	Conditional
N001: Inductively minimal geometries	14,519	7,371	1.969746
N003: Maximal symmetric markings	17,780	9,155	1.942108
N008: Frattini coordinate geometries	18,009	11,132	1.617769
L030: Disjoint-subset geometries	22,704	12,286	1.847957
L040: High-rank symmetric markings	51,894	29,321	1.769858

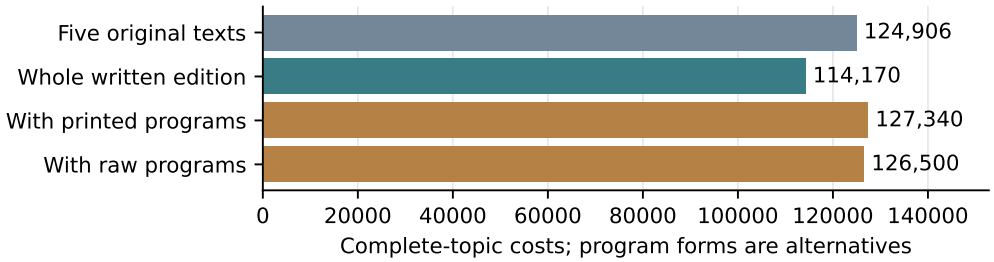
Every conditional factor presupposes acquisition of the *whole current common theory and all four complete declared programs*. Each local paper, including context and references, is then charged in full. The common cost is 44,905 characters.

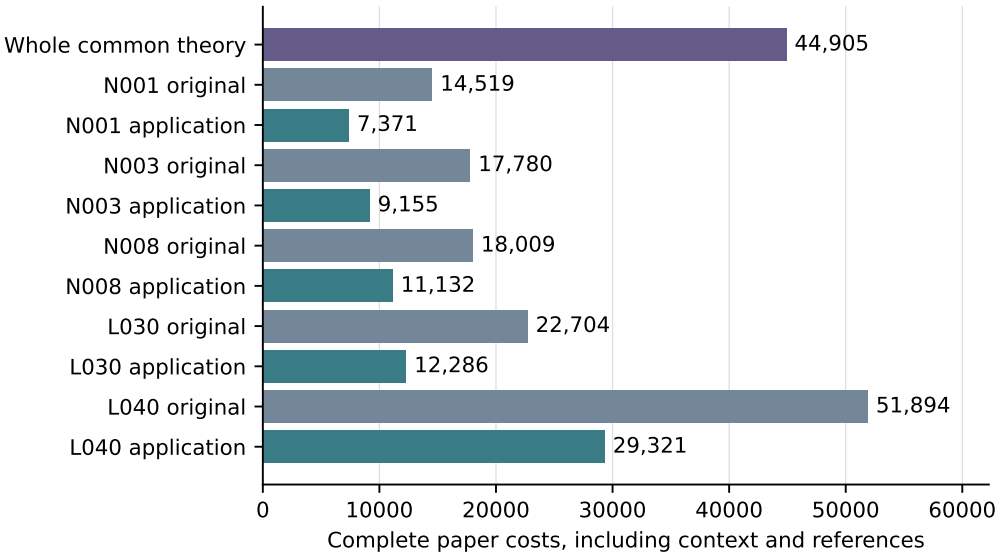
Complete-topic boundary	Denominator	Factor
Written common and all five applications	114,170	1.094035
Also the entire printed program appendix	127,340	0.980886
Also the four whole raw programs (alternative)	126,500	0.987399

The appendix costs 13,170 characters; the raw files cost 12,330. These are alternative representations, never additive charges. One program supplies bounded primitive-group inputs, two validate written general arguments, and one supplies the separate degree-eight example and branching-presentation check. No program is pruned because its role is auxiliary.

Two current operational drivers (15,442 characters) and two Lean files (8,377 characters) are separately inventoried. The fourteen reused declarations remain partial formal evidence. Full external proof, graphical and historical software costs remain unknown, not zero. No source, question or formal credit changes.

Whole theory and complete applications





The lower bars compare full paper costs. Their conditional ratios require the common theory and complete programs already to have been acquired. The current written denominator pays the common paper once; it does not omit it or add both prior common papers.

NFC nonspace sensitivity	Original total	Written total	Factor
Complete raw text (primary)	124,906	114,170	1.094035
Selected literal text	123,210	114,118	1.079672
Selected calibrated text	123,210	114,118	1.079672
L040 article-only, otherwise primary	124,125	114,170	1.087195

The primary counts raw, untrimmed NFC nonspace characters. All thirty settings—three extraction conventions, two normalizations and five units—are retained. The separate direct L040 article-only input changes only that source cost; all replacement costs and the other four conditionals stay unchanged. Complete JSON and CSV records give 240 main exact fractions and 120 cover-sensitivity fractions.

The earlier numerical edition is preserved. These results reuse the independently accepted inputs; no source extraction, font calibration, GAP or Lean is rerun here. The numerical author also authored those inputs, which received distinct root acceptance. This numerical candidate still requires its own independent review.
