LCD manuscript inputs

Whole sources, common theory and both applications

The input boundary contains five complete PDFs and 69 physical pages: both originals, the whole accepted common paper, and both complete accepted applications. No comparison factor is calculated in this input proposal.

The coordinate was fixed before counting: selected, visibly calibrated text, NFC normalization, characters without whitespace. The following lengths are individual input observations; they are not compression claims.

Document	Pages	Raw	Calibrated	Repairs
L050 original	11	25,023	24,674	37
F017 original	17	34,431	34,082	84
Complete common paper	14	32,319	32,300	147
F017 application	12	29,469	29,454	18
L050 application	15	37,453	37,432	28

"Raw" includes exact extracted running furniture. "Calibrated" removes only the specified running headers or isolated page numbers and repairs the occurrence-bound glyph aliases. Every title, abstract, body page, footnote, mathematical table and reference remains. The selected uncalibrated text is also recorded. The JSON supplies all five units, NFC and NFKC, and all three variants: 150 metric cells with text hashes. Printed line hyphens and source mathematical errors are unchanged.

The L050 original is the eleven-page published article by Leemans and Rodrigues, *Linear codes with complementary duals from some strongly regular subgraphs of the McLaughlin graph*. The F017 original is the seventeen-page author manuscript by Key and Rodrigues, *LCD codes from adjacency matrices of graphs*, dated 4 August 2017. The common paper is the exact accepted fourteen-page edition. The twelve-page F017 application is separately accepted with 104 source dispositions and seven retained input classes. The fifteen-page L050 application has 54 dispositions and its exact retained classification inputs. Both applications reuse the same nine scoped generic Lean declarations; these do not formalize either complete source.

No executable listing occurs in these five PDFs. Accordingly, the symmetric manuscript policy removes no code block here. Mathematical algorithms stated in prose and their proofs remain. The complete required certificate files stay explicit proof premises outside manuscript length, with optional validation kept distinct. Unavailable original software is unknown, not zero.

Glyphs and remaining dependencies

The actual-font audit reconciles 2,179 encoded Type1 glyph classes. The source, common and L050-application Type1 text is fully aligned; the F017 application has unchanged Type0 Unicode text dictionaries, identified separately. A total of 314 occurrence-bound repairs have exact dictionary, encoding, byte and event evidence. They include printable sum/product aliases and styled letters as well as control and private-use glyphs. The mapsto tail and its adjacent arrow remain separate events. Ordinary ligatures are preserved; normalization sensitivity remains visible.

All eleven L050 pages, fourteen common pages and fifteen L050 application pages were freshly viewed. The exact earlier seventeen-page F017 source views and twelve final application views are reused explicitly. In addition, 267 embedded-outline classes were viewed. One outline-panel label has a font warning for a combining circle; the actual embedded circle outline is visible and inspected. No primary PDF, extracted source text, font bytes or source image is distributed with this checkpoint.

The whole-file inventory preserves 127 declared occurrences and counts 102 unique complete contents once by exact hash. It includes 20 required programs, two complete derived GAP certificates, 19 required data files and 42 complete finite records. Two optional validation programs with one auxiliary record, eleven operational drivers, two partial Lean files and three scope records remain separate. All 102 contents have whole-byte pins and ten raw-text coordinates, giving 1,020 cells. No file is shortened by removing diagnostic branches. No large enumeration, formal compilation or scientific proof review is repeated by this audit.

Any eventual written comparison pays the whole common paper once and both complete applications. A conditional comparison requires prior acquisition of the entire common paper and all declared required certificates and data. Old migrated local notes are provenance, not uncharged current prose premises. No overlap with another topic is treated as free. Both scientific applications are accepted; this input proposal still requires distinct review. Historical pending-review wording inside immutable author PDFs predates those acceptances.

Full retained classical proofs, source software, graphics and formula layout, external libraries and complete formalization have unknown costs. No raster image XObject occurs in these PDFs, but this does not measure mathematical layout or vector complexity. The comparison is extracted text, not a claim to recover every aspect of the visible page. There is no software-inclusive factor, original credit or question credit from this input preparation.

The portable checker re-extracts all pages, checks the precount policies and whole-file pins, and exercises 25 corruption controls. All 120 PDF cells and 450 file cells from the earlier four-document checkpoint are unchanged. This additive complete input edition preserves the fixed metric, raw sensitivities and explicit unknown costs.
